

PROJECT DESIGN PHASE

Solution Architecture

Date	01 October 2026
Team ID	SWTID-2026-4057
Project Name	Implement Client Script & UI Policy (Incident)

1. Architecture Overview

The solution architecture is a ServiceNow Incident interface control architecture. Incident users interact with the Incident form or Incident list. The ServiceNow client-side control layer evaluates field conditions and user actions through the configured UI Policy and Client Scripts. The controls then update, validate, or restrict the Incident record before the user completes the intended action.

2. Logical Solution Architecture

Incident User Creates / updates Incident	→	ServiceNow Incident UI Form + List
	↓	
UI Policy Layer High Impact Control Impact = 1 - High	→	Field Controls Assignment group mandatory Urgency read-only
	↓	
Client Script Layer onChange • onSubmit • onCellEdit	→	Validation & Interaction Control Auto-set Urgency Block invalid save Block State list edit
	↓	
Feedback to User Info / Error / Alert messages	→	Incident Record Valid update is accepted

3. Architecture Layers and Responsibilities

Layer	Elements	Responsibility
User Interaction	Incident User; Incident Form; Incident List	Provides the interface through which Incident data is entered or modified.
UI Policy	High Impact Control; UI Policy Actions	Dynamically applies field behavior when Impact is 1 - High and reverses it when the condition is false.
Client Script	onChange; onSubmit; onCellEdit	Automates field values, validates save conditions, and controls list editing behavior.
Feedback	Info message; Error message; Alert	Communicates automatic actions, validation failures, and restricted operations to the user.
Data	Impact; Assignment group; Urgency; Assigned To; State	Stores the Incident values affected by the implemented controls.

4. Control Flow

High Impact form flow: Impact = 1 - High → UI Policy activates → Assignment group becomes mandatory and Urgency becomes read-only → onChange sets Urgency to 1 - High.

Save validation flow: User selects Save → onSubmit checks Impact and Assigned To → if High Impact + Assigned To empty, save is blocked and an error is shown → otherwise the update is allowed.

List edit flow: User attempts to edit State from the Incident list → onCellEdit executes → an alert is displayed → callback(false) blocks the list edit → user is directed to open the Incident.

Reverse flow: Impact changes from High to another value → Reverse if false restores the normal UI Policy behavior → Urgency becomes editable and Assignment group is no longer forced mandatory by this policy.

5. Technology and Configuration Mapping

Architecture Element	ServiceNow Implementation
Application platform	ServiceNow
Business record	Incident [incident] table
Dynamic field policy	UI Policy – High Impact Control
Field-level behavior	UI Policy Actions for Assignment group and Urgency
Event-driven automation	onChange Client Script on Impact
Submission validation	onSubmit Client Script
List interaction control	onCellEdit Client Script on State
Client-side language	JavaScript

6. Architecture Benefits

- Immediate field behavior based on Incident conditions.
- Consistent handling of High Impact incidents.
- Prevention of incomplete High Impact submissions.
- Controlled State updates through the Incident form rather than direct list editing.
- Clear user feedback through information, error, and alert messages.
- Reversible policy behavior when the High Impact condition is no longer true.

7. Conclusion

The solution architecture connects the Incident user interface with a focused set of ServiceNow UI Policies and Client Scripts. The architecture keeps the implementation within the Incident interface while providing dynamic field control, automatic updates, submission validation, list-edit restrictions, and immediate user feedback.
